ŀ	Four hundred-eighty sera from patien	ts	with hope	titis were	tested for		

Four hundred-eighty sera from patients with hepatitis were tested for leptospiral agglutinins by Microscopic Agglutination (MA) test. Twenty-one sera (4.4%) were positive at a significant titer of 1:128 or greater. The most predominant reacting serotypes were L. icterohemorrhagise, L. canicola and L. grippotyphosa. The importance of considering leptospirosis among other infectious diseases in jaundiced patients is stressed.

siedicai Editor NAMRU-3 FPO New York 09527 One of the several diseases that may cause jaundice in humans is ieptospirosis (Turner, 1969). In Egypt, jaundiced patients usually are checked for infectious and serum hepatitis but not for leptospirosis. In this study, the presence of leptospiral agglutinins in sera, from patients from six hospitals in Cairo in 1970 diagnosed as having clinical hepatitis is reported.

MATERIALS AND METHODS

Four-hundred-eighty sera from patients in Abbassia Fever Hospital. Embaba Fever Hospital, Mounira Hospital, Shoubra Hospital, Azhar and Agouza Hospitals were tested for leptospiral agglutinins by the Microscopic Agglutination (MA) test (Gochenour, et. al., 1953). These sera were from jaundiced patients and were tested primarily for hepatitis-associated Australia entigen.

Sera were first screened at a final dilution of 1:128 against the collowing leptospira scrotypes: ballum, canicola, icterohemorrhagiae, bataviae, grippotyphosa, pyrogenes, autumnalis, pomona, woiffi, austreiis, hebdomadis, tarassovi, javanica, butembo, palve and andamana. (These scrotypes were originally supplied by the Pathological Department of the U.S. Naval Medical Pescarch Unit No. 2, Taipei, Taiwan). Sera which agglutinated one or more leptospira scrotypes were titrated against each agglutinating scrotype. The procedure for this test has been described previously (Barsoum & Jamison, 1971).

RESULTS

Twenty-one (4.4%) of the 480 human sera tested showed reptospiral agglutinins at a titer of 1:128 or greater. This titer constitutes presumptive evidence of infection with the organism dating back from the preceding week to several years

(Alexander et. al., 1970). MA test results for different hospital patient are given in Table 1. Patients from the Abbassia Fever Hospital showed the highest incidence of leptospiral sero-positivity (10/198). Seven sera were found to have agglutinins that reacted with L. ictorohemorrhagiae, seven with L. canicola, four with L. grippotyphosa, two with L. australis and one with L. tarassovi (Figure 1). Sixteen of the twenty-one positive sera for leptospirosis were negative for hepatitis - associated Australia antigen. The remaining sera were positive at different titers by complement fixation test against Australia antigen.

TABLE 1: Leptospiral Microscopic Agglutination (MA) test results on 80 sera from jaundiced patients in six hospitals in Cairo, Egypt, 1970.

		Leptospiral MA result			
Source of samples	Number of sera tested	Number positive at 1:128 titer or greater	Positive serotype(s)		
Shigaria Wever Hospital	198	10	icterohemorrhagiae (4) grippotyphosa (3) australis (2) canicola (1)		
Embaba Fever Hospital	83	4	icterohemorrhagiae (1) canicola (1) grippotyphosa (1) tarassovi (1)		
Mounira Hospital	77	2	icterohemorrhagias (1) canicola (1)		
Agouza Hospital	70	3	canicola (3)

Azhar Hospital	25	1	canicola (1)		
IOTAL	480	21 (4.37%)			

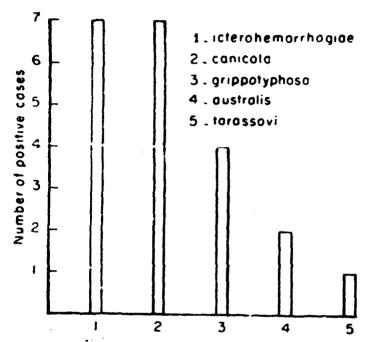

Fig. 1 Histogram of the frequency of leptospiral serotypes reacting with 480 sera from Jaundiced patients.

Aboussion

The frequency of leptospiral seropositivity of all patients with hepatitis (21/480) was not significantly different from that of apparently healthy persons (3/80) or abattoir workers (2/101) (Maronpot & Barsoum, 1972). The seropositivity among these patients was also less than that found in Tanta Hospitai patients (23/270) (Barsoum & Jamison, 1971). Sixtythree sera taken from patients with different diseases from the Abbassia Fever Hospital in 1970 were 100% seronegative for leptospirosis. However, from the same hospital, ten of 198

Patients with hepatitis showed leptospiral agglutinins rificant titers of i:128 or greater. It should be noted that: 1. L. leterohemor englis and L. conicola were the predominant scrotypes in this group of patients, and 2: that L. keterohemorchagiae often causes severe illness characterized by jaundice and conal failure. Occasionally, however, other serotypes may preduce an identical clinical picture of equal severity (Galton at. al., 1962 . In previous serologic surveys in Egypt, L. grippolyphosa was the predominant scrotype in a random selection of normal and hespital pointainess. (McGuire & Myers, 1957; Annady (1 cm. 1962) Hamed, 1969; Barssonn & Jamison, 1971). The most common probable sources of human leptospirosis are various species of domesticated and wild animals; infection results from direct or indirect contact with urine of infected animais (Garton et. al., 1962). Agglutinins to L. icterohemorthagac were proviously detected in sera of pigs, dogs, buffalo and sheep; L. grippotyphosa antibodies were found in mice, buffalo and con sera: L. cane viu antibodies in sera of dogs and pigs, and L. Jarassori in cow sera (Maronpot and Barsoum, 1972. Moreover, L. canicola was isolated in Egypt from dog kidneys and urine (Marospot et al., 1971). L. icterohemorrhagiae was isolated from mongeose and L. grippotyphosa from mice (Berseum & Raiser 1972, unpublished results).

Leptospirosis recently has been reported to be a significant cause of jaundice in South Sumatra (Fresh et. al., 1971). In Egypt, leptospirosis in addition to other infectious diseases must also be considered in the differential diagnosis of jaundiced patients.

SUMMARY

Four hundred-eighty sera from patients with hepatitis were tested for leptospiral agglutinins by Microscopic Agglutination

(MA) test. Twenty-one sera (4.4%) were positive—at a significant titer of 1:128 or greater. The most predominant reacting serotypes were L. leteroheme rhagine, L. cankola and L grippotyphosa. The importance of considering leptospirosis among other infectious diseases in jaundiced patients is stressed.

ACTROWLEDGMENTS

The authors wish to thank Dr. J. Fresh, Deputy Director, NAMRU-2 and Dr. G. Higashi, Head, Immuno-Parasitology Department, NAMRU-2, for their advices and thorough revision of the manuscript.
